} xdot;

xdot* parseXDotF (char*, drawfunc_t opfns[], int sz);
xdot* parseXDot (char*);
char* sprintXDot (xdot*);
void fprintXDot (FILE*, xdot*);
void freeXDot (xdot*);

xdot_grad_type colorType (char*);
xdot_color* parseXDotColor (char*);
void freeXDotColor (xdot_color*);

DESCRIPTION

*libxdot* provides support for parsing and deparsing graphical operations specified by the *xdot* language.

Types

**xdot**

This encapsulates a series of *cnt* xdot operations, stored in the array pointed to by *ops*. The *sz* indicates the size of each item stored in *ops*. If the user sets the *freefunc* field, this function will be called on each item in *ops* during *freeXDot* before the library does its own cleanup of the item. This allows the user to free any resources stored in the item by using an expansion of the *xdot_op* structure.

**xdot_op**

A value of this type represents one xdot operation. The operation is specified by the *kind* field. The corresponding data is stored in the union *u*, with the subfield associated with a given *kind* indicated by the comments.

The *drawfunc* field allows the user to attach a drawing-specific function to the operation, providing an object-based interface. These functions can be automatically attached during parsing by providing a non-NULL second argument to *parseXDotF*.

**xop_kind**

This type provides an enumeration of the allowed xdot operations. See http://www.graphviz.org/doc/info/output.html#d:xdot for the specific semantics associated with each operation.

**xdot_rect**

This represents a rectangle. For ellipses, the *x* and *x* fields represent the center of the rectangle, and *w* and *h* give the half-width and half-height, respectively. For images, (*x*,*y*) gives the lower left corner of the rectangle, and *w* and *h* give the width and height, respectively.
**xdot_polyline**
This type encapsulates a series of cnt points.

**xdot_text**
A value of this type corresponds to printing the string text using the baseline point \((x,y)\). The width field gives an approximation of how wide the printed string will be using the current font and font size. The align field indicates how the text should be horizontally aligned with the point \((x,y)\).

**xdot_image**
This denotes the insertion of an image. The image source is given by name. The images is to be placed into the rectangle pos.

**xdot_font**
The fields give the name and size, in points, of a font.

**xdot_align**
This enumeration type corresponds to the xdot alignment values -1, 0 and 1 used with the text operator, or '\l', '\n' and '\r' used in dot text.

**Functions**

`xdot* parseXDotF (char *str, drawfunc_t* opfns, int sz)`
- Parses the string str as a sequence of xdot operations and returns a pointer to the resulting xdot structure.
- The function parses as many xdot operations as it can. If some unknown or incorrect input was encountered in str, the ops and cnt fields will reflect the operations parsed before the error, and the XDOT_PARSE_ERROR bit will be set in the flags field. The function returns NULL if it cannot parse anything.
- If sz is non-zero, it is assumed to be the size of some structure type containing xdot_op as a prefix. In this case, the elements in the array pointed to by ops will each have size sz.
- If opfns is non-zero, it is taken to be any array of functions indexed by xop_kind. During parsing, the drawfunc member of xop_op will be set to the corresponding function in opfns.

`xdot* parseXDot (char *str)`
This is equivalent to `parseXDotF(str, 0, 0)`.

`void freeXDot (xdot* xp)`
This frees the resources associated with the argument. If xp is NULL, nothing happens.

`extern char* sprintXDot (xdot* xp)`
`extern void fprintXDot (FILE* fp, xdot* xp)`
- These two functions deparse the argument xdot structure, producing a string representation. fprintXDot writes the output onto the open stream fp; sprintXDot returns a heap-allocated string.
- The color string with fill and draw operations can encode linear and radial gradients. These values are parsed automatically by parseXDotF or parseXDot, with xdot_op having kind xd_grad_pen_color or xd_grad_fill_color and the value is stored in grad_color.
- For an application that handles its own parsing of xdot, the library provides three helper functions.

`xdot_grad_type colorTypeXDot (char *str)`
returns the color type described by the input string.

`char* parseXDotColor (char *str, xdot_color* clr)`
- attempts to parse the string str as a color value, storing the result in clr. It returns NULL on failure.

`void freeXDotColor (xdot_color* cp)`
This frees the resources associated with a value of type xdot_color.
BUGS
Although some small checking is done on the sz argument to parseXDotF, it is assumed it is a valid value from sizeof applied to some structure type containing xdot_op as its first field. There can be no validation of the opfns argument.
